TITLE: Effect of exit edge thickness on characteristics of turbine guide lattices
ACB
ASBSOURCE: Teploenergetika,¹⁰ no. 8, 1963, 24-28

TOPIC TAGS: turbine, guide vane, blade, lattice profile, profile loss

ABSTRACT: A detailed investigation has been made of the exit edge thickness effect on turbine characteristics for mach numbers 0.2-1.2. Variation in thickness is achieved by changing the contour of the profile only on the concave side of the vane (see Enclosure 1). The selected lattice is type TS-1A with exit edge thickness of 1 mm. The pressure distribution on the lattice profiles is obtained for various values of blade pitch \bar{t} , edge thickness Δ , and mach numbers (see Enclosure 2). The effect of exit edge thickness was studied on lattice profile losses, on end losses, and on total turbine efficiency loss. Changing the thickness on the concave side, but leaving the effective exit velocity angle and lattice width constant, induces a significant decrease in profile losses with an increase in the magnitude of Δ . On the other hand, at large mach numbers, a critical increase in

TITLE: New supersonic nozzle grates from the Moscow River Engineering Institute

CITED SOURCE: Tr. Mosk. energ. in-ta, vy*p. 47, 1963, 5-16

TOPIC TAGS: supersonic flow, nozzle grate, gas dynamics

TRANSLATION: The authors describe an empirical method of constructing supersonic nozzle grates. They give formulas for determining the basic geometric dimensions of these grates and describe the results of experiments on several grates constructed by the suggested method. The grates studied differ from those employed earlier in the authors' studies by a smaller variation of the loss coefficient in uncomputed states. The proposed grates have longer interblade channels than those constructed by the method of characteristics with an angle point in a narrow cross-section (Ferry, A., Aerodynamics of Supersonic Flow, Gostekhizdat, 1952, pages 176-184). TITLE: Investigation of the transition of a turbulent into a laminar boundary layer

SOURCE: Inzhenerno-fizicheskiy zhurnal, no. 4, 1964, 18-24

TOPIC TAGS: Turbulent boundary layer, laminar boundary layer, turbulent flow, laminar flow

ABSTRACT: Experimental investigations of a boundary layer on different models confirmed the transition of a turbulent boundary layer into a laminar one, i.e., a "reverse transition" of great positive longitudinal velocity. Maximum positive velocity gradients must meet the transonic gas flow. Consequently, transition through the sonic velocity in convergent-channel flow is always associated with a degeneration of turbulence and the linearization of the core flow and of the boundary layer. This phenomenon (reverse transition) should be considered a very important feature of the transonic flow of a viscous gas. The experiments showed that the transition of a turbulent boundary layer occurs

Card 1/2

ACCESSION NR: AP4038658

gradually over a considerable "transition" portion. According to preliminary data, the distance at which a "reverse" transition occurs is of the order of $15-25 \delta$, where δ is the thickness of the boundary layer at the start of the transition zone. However, the length of the transition zone should depend on the value of the velocity gradient. Orig. art. has 5 figures.

TITLE: The Route of Friendship (Doroga druzhby)

PERIODICAL: Znaniye - Sila, 1957, # 10, pp 29 - 32 (USSR)

ABSTRACT: The article gives the history of attempts at achieving rail communication between the Soviet Union and China. The construction of such a rail-road line from Central China, via Tyanshuy, Liangshow and Urumchi, to the Kazakh Republic, "The Route of Friendship", was begun in 1953 in the Chinese first Five-Year-Plan. In addition there is now a motor-road connecting China and Tadzhikistan. The construction of Chinese railway lines is being carried out with full speed and is causing a great transformation in the north-western part of China as to development of building industry, aviation, and urbanism. The present city of Liangshow is a brilliant example of this. In accordance with established projects this city will undergo extensive development. There are 4 sketches and 1 map.

TITLE: Contribution to the study of the resistance of the sunflower (*Helianthus Annuus L.*) to the sunflower broomrape (*Orobanche Oumana Wallroth*)

SOURCE: Bulgarska akademiya na naukite, v. 18, no. 2, 1965, 153-156

TOPIC TAGS: plant disease, plant parasite, plant chemistry

ABSTRACT: [German article] In spite of numerous studies of cultivated plant immunity, the sunflower resistance to the *Orobanche* parasite is still far from being understood. Two facts prompted the authors to undertake the study of the subject. Firstly, there exists in Bulgaria a large number of well-balanced self-pollinated sunflower lines exhibiting varying degrees of broomrape resistance (A. Popov, M. Lazarov, Izv. in-ta rasteniyev'dstvo, 1963, book XVI). Secondly, recent investigations of potato immunity to certain fungus diseases link the immunity with the chlorogenic acid content in the tuber periderm cells. Consequently, the authors began to study the content of this acid in the resistant and nonresistant sunflower strains. The results show that, generally, the resistant strains have a lower acid content than.

Card 1/2

L 4352-66

ACC NR: AP5028776

the nonresistant strains. Particularly striking is the fact that broomrape infected plants show a 6-12 times larger chlorogenic acid content than the noninfected ones of otherwise nonresistant strains. The article concludes with possible explanations of the results of the investigation. The work was presented by A. Popov, Academician, 18 Sep 64. Orig. art. has: 1 table. [JPRS]

News in Brief

PERIODICAL:

Zavodskaya laboratoriya, 1959, Vol 25, Nr 8, pp 934 - 935
(USSR)

ABSTRACT:

A. Ya. Mashukov reports that the Institute prepared test samples containing several rare elements. For the preparation they used a copper-zinc ore (0.0009% In, 0.007% Tl, 0.0012% Ga, and 0.0003% Ge) and not-calcined lead dust (0.004% In, 0.032% Tl, 0.0001% Ga, and 0.0009% Ge). The composition of the test samples was determined by three institutes. M. M. Lazarev (Laboratoriya zavoda) (Plant Laboratory) recommends a nephelometric method for the determination of zinc in the alloy MA-2 by a reaction with potassium ferrocyanide using a photocalorimeter PEK-M. Yu. M. Gofman describes a method for the non-cutting analysis of low alloy steels 15M, 12MKh, 12KhMF for the determination of the carbides of manganese, chromium, molybdenum, and vanadium. The analysis can be made without preparation of a sample by photocalorimetry directly on the surface of the workpiece in-

TITLE: A device for measuring the total pressure in the face sections of a gas mask.
Class 42, No. 181359 [announced by the Military Academy of Chemical Protection
(Voyennaya akademiya khimicheskoy zashchity)]

SOURCE: Izobreteniya, promyshlennyye obraztay, tovarnyye znaki, no. 9, 1966, 97

TOPIC TAGS: gas mask, pressure measurement

ABSTRACT: This Author's Certificate introduces a device for measuring the total pressure in the face sections of a gas mask. The unit contains a base and a sectional model of a head which is divided along the cross section. One of the parts of this model is fastened to a dynamometric spring element and connected to a force measuring mechanism, while the other is mounted on a feed mechanism. Measurement accuracy is improved by making the model in the form of two spherical sections with different diameters and a flat base at the point of junction.

The importance of the subtilizable layers of black soils to plant nutrition. N. M. Lazarev, V. N. Belyakina, A. N. Pertseva, and V. F. Lasko. *Trudy Vsesoyuz. Nauch.-Issledovatel. Inst. Selskogo Merkotil.* 8, 11-21 (1951).—Preliminary set of expts. was made with following 3 types of soil: (1) Southern black soil of the South-Eastern Inst. of Grain Economy with soil layers 0-18, 19-27, and 28-50 cm. deep; (2) humus-carbonaceous soil from the Leningrad-Kingsepsk region, with soil layers 0-20, 21-35, and 36-50 cm. deep; (3) miltargillaceous loamy soil from the Lakhta station of the Leningrad region, with soil layers 0-18, 19-35, and 35-50 cm. deep. It was found that total N values decreased with the depth of soil layers; the nitrate N was of equal value in the upper 2 layers of soil (1) and considerably reduced in the 28-50 cm. layer. In the podzolic soil, the biol. activity, which is generally low in the upper layers, is practically absent in the deeper soil layers. The second series of plant-growing expts. were carried out in pots 20 cm. high when individual soil layers were tested and in pots 60 cm. high when the total 3 soil layers were tested integrally. Plant yields in dry wt. were practically the same in each of the 3 soil layers at normal pH. When the pH was lowered the yield in the subarable layers was reduced. In the 60-cm. pots, in which the total of 3 soil layers were tested, the yield in the case of soil type (1) was greater than the total of the yields of its individual constituent layers. In the podzolic soil the yield of the entire 3-layered test was smaller than in the single 0-17 cm. layer owing to the fact that the root system extended into the poorer lower soil layers. Knowledge of this has an important bearing on the application of deep-soil fertilization and microbioactivation in different crops, especially in the case of perennial grasses.

✓ Stability of the structure of soils in relation to their content of different forms of humus. N. M. Lazarev and E. A. Nikitina. *Trudy Vsesoyuz. Nauch.-Issledovatel'stva po Soiolkhоз. Mikrobiol.*, 8, 33-41 (1953). — The formation of H₂O-impermeable soil aggregates is closely associated with the process of formation and decomposition of soil humus, according to which soils can be classified in relation to their structure stability as (1) primary, in which the α -humates predominate, and (2) secondary, in which the β -humates predominate. In relation to the soils' ability to absorb and retain H₂O both types play an equal role, but their effect on plant nutrition is different. The adhesive and cementing properties of soil of type 1 predominate in acid soils, the humus of which is easily attacked by the soil microflora; it is rich in N totally available to the plant nutrition via the root system. Aggregate structures of soils of type 2 are predominant in base-sat'd. soils, its humus is free of protein-complexes and is ineffectively attacked by soil microflora, which in turn explains the high stability of the structure of soils of type 2; its value as a nutritional medium is low. In most black soil, aggregates of soil structure type 1 far exceed those of 2, hence their high fertility. As a result of harrowing and continuous cultivation of arable black-soil the α -humus part is first to undergo decomposition, resulting in the general reduction of its structural aggregates and in a sharp rise in the sp. gr. of the β -humus aggregates. Most valuable from the agricultural viewpoint is the soil structure consisting of mixed α - β aggregates which predominate in virgin soils and in grass-growing base-sat'd. soils.

✓ The role of microorganisms in hydroponic plant nutrition.

N. M. Lazarov and L. M. Dorosinskii. *Troye Vsesoyuz.*
MD *Nauk Chetvredatel. Inst. Sel'skogo, Mikrobiol.* 8, 67-73
(1963).—The liquid medium of Bryanskikh and the
general technique of Shulov were used. Oats were grown 1)
under sterile conditions in liquid culture without aeration, 2)
the same with aeration, 3) in the presence of soil bacteria
without aeration, and 4) the same with aeration. Results
tentatively indicated that in liquid culture plants can de-
velop by assimilating mineral nutritive matter in the com-
plete absence of bacteria. The introduction of soil bacteria
may prove favorable or unfavorable depending upon the
degree of liquid culture aeration. In the absence of aeration
conditions are created which are more favorable to the de-
velopment of anaerobic microfauna and which lead to the ac-
cumulation of bio-end products such as fatty acids and reduc-
ing substances, all of which depress the plant growth. Under
conditions of aeration the aerobic types of microfauna de-
velop, especially those which decompose humus.

TITLE: Multiply-charged particles from cosmic-ray stars

SOURCE: Akademiya nauk Kazakhskoy SSR. Institut yadernoy fiziki. Trudy, v. 5. Alma-Ata, 1962. Fizika chastits vysokikh energiy. Struktura yadra, 96-101

TEXT: The authors studied multiply-charged particles (fragments) from cosmic ray stars produced in emulsions at a height of about 30 km. The charge of a fragment that is stopped in the emulsion can be found from the width of the last 150μ of its track. The unstable ^3Li particles have an angular distribution that is nearly isotropic and an energy spectrum that agrees well with that predicted by the evaporation theory, therefore most of the ^3Li particles are probably evaporated from excited nuclei. The stable particles with $Z = 3$ and energy greater than 60 Mev have a strongly anisotropic angular distribution (the ratio of the numbers in the forward and back directions is 45/2) and an energy spectrum that cannot

Card 1/2

Multiply-charged particles ...

S/707/62/005/000/007/014
D290/D308

be described by the evaporation theory; these particles probably originate in a cascade process. The angular and energy distributions of fast particles with $Z \geq 4$ agree with the hypothesis that they are produced in a cascade process. The charge distribution of the fragments decreases less sharply with Z than in Nakagawa's work (Ref. 3: Nakagawa, S., J. Nuovo Cim., 9, 780, 1958). The probability of emission of a fragment depends on the number of grey tracks in the star and not on the number of fine tracks. There are 8 figures.

TITLE: An Investigation into the Possibility of Autonomous Supply
of the Auxiliary Power Requirements of High-voltage Mercury
Valves. (Issledovaniye vozmozhnostey avtonomnogo pitaniya
sobstvennykh nuzhd vysokovol'tnykh rtutnykh ventiley)

PERIODICAL: Vestnik Elektropromyshlennosti, 1957, Vol.28, No.9,
pp. 3 - 8 (USSR).

ABSTRACT: The rectifier/inverter sub-stations of high-voltage d.c.
transmission systems use bridge-connected rectifiers whose
cathodes may be at very high voltages to ground. The mercury
valves require some 1 - 3 kW of auxiliary power, at cathode
potential, for ignition excitation, anode heating, and electrode
control. It is very difficult to supply the power at the ne-
cessary voltage, and special isolating transformers are used
which often require to be connected in cascade. It has recently
been proposed to tap the power from the damping circuit between
the valve anode and cathode. This circuit comprises a series
capacitance and resistance used as a potential divider and is
usually an essential part of the converter. Control signals are
Card 1/4

An Investigation into the Possibility of Autonomous Supply of the
Auxiliary Power Requirements of High-voltage Mercury Valves.

110-9-2/23

transmitted by a modulated light ray which acts on a photo-cell operating at valve potential. The method obviates an isolating transformer and is simpler and cheaper. The principles of tapping power from the damping circuit are then explained. Fig.1 shows the valve bridge of a rectifier/inverter sub-station for the d.c. Stalingrad-Donbas system. The rated voltage of the bridge is 100 kV and the transmitted current 900 A. The three-phase output of the transformer is at 83 kV. The principal operating conditions of a sub-station are considered and an expression is written for the voltage in each case. It is shown that the inverse-voltage contains only the fundamental frequency and multiples of three. The relationship between the harmonic content of the voltage and the fixing angle is shown in Fig.2 and it is concluded that a filter must be provided in order that power may be tapped from the damping circuit. The corresponding circuit is shown in Fig.3a. The only additional equipment required is a transformer with an insulation level of 10 kV. The procedure for calculating the maximum power from a tapping is described and the simplifying assumptions underlying the calculation are stated. A vector diagram for the equivalent circuit (Fig.3b) is used to construct graphs of the active

Card 2/4

110-9-2/23

An Investigation into the Possibility of Autonomous Supply of the
Auxiliary Power Requirements of High-voltage Mercury Valves.

(Fig.4) and reactive (Fig.5) power as functions of the circuit parameters. Fig.6 gives the reactive power and the loss in the choke coil as functions of the capacitance for various values of the capacitance in the damping circuit. Hence, the useful power from the tapping is determined and it is shown that some increase in the capacitance of the damping circuit extends the useful range of power tapped. The power calculations were verified experimentally on a model of the circuit. The damping and tapping circuits were connected in parallel with a thyratron model of a power system sub-station. Voltage oscillograms were taken with firing angle values and transmitted current corresponding to the main operating conditions. The results were worked out on a scale corresponding to the Stalingrad-Donbas scheme and showed that for firing angles close to 0 or 150° (which correspond to normal transmission conditions) the voltage waveform was satisfactory. For angles near 90° the voltage waveform was very distorted. This was because of insufficiently-close tuning of the tapping circuit and non-linearity of the inductance of the choke. If the choke is linear the voltage distortion is much less. For firing angles close to 0 and 150° the tapped voltages and power are in good agreement with the

Card 3/4

110-9-2/23

An Investigation into the Possibility of Autonomous Supply of the
Auxiliary Power Requirements of High-voltage Mercury Valves.

calculated values. The proposed circuit has a number of advantages compared with supplies from isolating transformers. It requires only a capacitor, a transformer and a choke, with an insulation level of 10 kV, which are much cheaper than an isolating transformer with an insulation level of 400 kV. A disadvantage of the system is the need to raise the capacitance of the damping circuit. The circuit can be used for all transmission system valves except shunting valves. It can also be used successfully for low-voltage mercury-arc rectifiers in industry and traction to deliver power at voltages of 0.8 - 15 kV. It is best suited to sealed-off valves and has limitations when applied to pumped valves.

TITLE: Grid Control Arrangements for a Model of High-voltage
Direct-current Transmission (Ustroystva setochnogo
upravleniya modeli elektroperedachi postoyannogo toka
vysokogo napryazheniya)

PERIODICAL: Vestnik Promyshlennosti, 1958, Vol.29, No.3,
pp. 14 - 18 (USSR).

ABSTRACT: Extensive use is being made of models to study conditions
of high-voltage d.c. transmission. The high-voltage valves are
simulated by thyratrons and the grid control arrangements must
ensure successive ignition of the thyratrons in the correct
sequence. The basic principle of operation of the system of
grid control is that at the instant when the negative locking
voltage applied to the grid-cathode space of the thyratron
unlocks, there is applied to it the positive voltage of a
control impulse. The main properties required of the grid
control device for the model are listed.

The article then describes a thyratron capacitor system of grid
control with peaking transformers. A block diagram of the two-
impulse system of controlling the model is given in Fig.1. The
Card1/3 system consists of six channels with phase displacement of 60°

110-3-3/22

Grid Control Arrangements for a Model of High-voltage Direct-current Transmission

electrical. The operation of the circuit is described. By including the primary windings of the insulating transformers, as indicated on the diagram by dotted lines, it is possible to obtain on the grids of the model thyratrons four impulses displaced by 30° electrical. Oscillograms showing the voltage wave shape at input to and output from each block are attached to Fig.1. A schematic diagram of the control system of the model is given in Fig.2. Protective arrangements are briefly discussed.

In principle, the main thyratrons can be controlled directly from the peaking transformers. However, curvature of the impulse wave front does not exceed 4 - 5 V per electrical degree. The main disadvantages of control systems using peaking transformers are: high inertia; the difficulty of using separate (per phase) regulation of the extinction voltages of the thyra- trons on the inverter; and the impossibility of altering the width of the control impulse without changing the circuit. The article then describes the electronic system of grid control which obviates these defects: a block diagram is given in Fig.3. It, too, consists of six channels with phase displacement

Card2/3 of 60° electrical. The main elements of each channel are

described. A schematic diagram of the first channel of the control system is given in Fig.4 and explained in the text. The electronic control circuit is without inertia and ensures operation over the range of $\pm 60^\circ$ electrical. These circuits are not limited to models and are applicable to the control of ionic instruments in other fields. Their use with crystal triodes should increase reliability and life. There are 4 figures.

TITLE: Determination of the Commutation Angles of a Multi-phase
Rectifier Installation with Allowance for Ohmic Resistance
of the Circuit

PERIODICAL: Vestnik elektropromyshlennosti, 1959, Nr 9, pp 16-21(USSR)

ABSTRACT: Most publications on the theory of multi-phase rectifiers
ignore the influence of the ohmic resistance of the supply
circuit when determining the angle of overlap, and assume
that this interval, when two anodes conduct simultaneously,
depends only on the reactance. This assumption is good
enough for most industrial applications but resistance
must be taken into account in some cases. For instance,
it is pertinent in analysing the operation of locomotive
rectifiers, in multi-phase cascade high-voltage d.c.
generators and particularly in constructing models for the
experimental study of normal and fault conditions on
rectifier installations. In very large rectifier
installations the ratio of resistance to reactance in the
commutating circuit is very much lower than in small ones;
for example, in the Stalingrad-Donbas Transmission System
